Algorithm:

1. **Sample** (randomly) the number of points required to fit the model ( $\#=2$ )
2. **Solve** for model parameters using samples
3. **Score** by the fraction of inliers within a preset threshold of the model

**Repeat** 1-3 until the best model is found with high confidence

# Why multiple views?

- Structure and depth are inherently ambiguous from single views.

# Why multiple views?

# Perspective effects

# Motion

# Occlusion

Rene Magritte's famous painting *Le Blanc-Seing* (literal translation: "The Blank Signature") roughly translates as "free hand". 1965

If stereo were critical for depth perception, navigation, recognition, etc., then this would be a problem

# Multi-view geometry problems

- **Structure:** Given projections of the same 3D point in two or more images, compute the 3D coordinates of that point

# Multi-view geometry problems

- **Stereo correspondence:** Given a point in one of the images, where could its corresponding points be in the other images?

# Multi-view geometry problems

- **Motion:** Given a set of corresponding points in two or more images, compute the camera parameters

# Human eye

Rough analogy with human visual system:

Pupil/Iris – control amount of light passing through lens

Retina - contains sensor cells, where image is formed

Fovea – highest concentration of cones

# Human stereopsis: disparity

FIGURE 7.1

From Bruce and Green, Visual Perception,  
Physiology, Psychology and Ecology

Human eyes **fixate** on point in space – rotate so that corresponding images form in centers of fovea.

# Human stereopsis: disparity

**Disparity** occurs when eyes fixate on one object; others appear at different visual angles

From Bruce and Green, Visual Perception, Physiology, Psychology and Ecology

# Stereo photography and stereo viewers

Take two pictures of the same subject from two slightly different viewpoints and display so that each eye sees only one of the images.

# Autostereograms

Exploit disparity as depth cue using single image.

(Single image random dot stereogram, Single image stereogram)

# Autostereograms

# Estimating depth with stereo

- **Stereo:** shape from “motion” between two views
- We’ll need to consider:
  - Info on camera pose (“calibration”)
  - Image point correspondences

# Stereo vision

Two cameras, simultaneous views

Single moving camera and static scene

# Camera parameters

**Extrinsic** parameters:

Camera frame 1  $\leftrightarrow$  Camera frame 2

**Intrinsic** parameters:

Image coordinates relative to camera  $\leftrightarrow$  Pixel coordinates

- *Extrinsic* params: rotation matrix and translation vector
- *Intrinsic* params: focal length, pixel sizes (mm), image center point, radial distortion parameters

*We'll assume for now that these parameters are given and fixed.*

# Geometry for a simple stereo system

- Assume parallel optical axes, known camera parameters (i.e., calibrated cameras). **What is expression for Z?**

Similar triangles  $(p_l, P, p_r)$  and  $(O_l, P, O_r)$ :

$$\frac{T - x_l + x_r}{Z - f} = \frac{T}{Z}$$

$$Z = f \frac{T}{x_l - x_r}$$

disparity

# Depth from disparity

image  $I(x,y)$

Disparity map  $D(x,y)$

image  $I'(x',y')$

$$(x', y') = (x + D(x, y), y)$$

So if we could find the **corresponding points** in two images, we could **estimate relative depth**...

# Calibration with linear method

- Advantages
  - Easy to formulate and solve
  - Provides initialization for non-linear methods
- Disadvantages
  - Doesn't directly give you camera parameters
  - Doesn't model radial distortion
  - Can't impose constraints, such as known focal length
- Non-linear methods are preferred
  - Define error as difference between projected points and measured points
  - Minimize error using Newton's method or other non-linear optimization
